  - Behaviour
  - Dynamic Architecture

# Distributed Information System

- Information systems (ISs) as distributed systems are collections of software components, communicate and coordinate their actions via a middle-ware.
- The middle-ware can provide dynamic connections, e.g.
  - according to functionality (available services),
  - according to free resources,
  - according to policies of individual components, etc.
- A component of distributed IS can be also another IS (a well-established IS).

# Component-Based Software Engineering

- Software applications are assembled from components from a variety of sources.
- Different implementations but only one “black-box” specification of a component.
  - different programming languages, platforms, environments,
  - components aren't objects – independent of implementation,
  - components aren't services – one implementation can act as many services.
- Maximal reusability – hierarchical composition of components.
- Formal specification of component-based architecture?

# Architecture Description Languages

- Formal languages for conceptual specification of software architectures.
- Based on some formal model (Petri-nets, temporal logics, process calculus, etc.).
- Components, connectors, configurations, architecture patterns.
- Some problems:
  - domain specific design and implementation of an ADL,
  - formal specification is very difficult, even for simple systems,
  - support only static or “simple” dynamic architectures.

# Dynamic Architecture

- Runtime modification of architecture:
  - creation and destruction of components and connectors,
  - passing of components, connectors as ordinary messages,
  - dynamic updating (of implementation) of components.
- How to control runtime reconfiguration and reflect it at a design time?

# Outline

- 1 Introduction
  - Distributed Information System
  - Component-Based Software Engineering
  - Architecture Description Languages and Dynamic Architecture
- 2 Motivation
  - Basic Idea
- 3 The Framework
  - Vertical and Horizontal View
  - Behaviour
  - Dynamic Architecture

# Motivation

## Basic idea – a framework

Runtime support for formal design and implementation of an IS with dynamic component-based architecture.

- The framework will act a middle-ware providing connectors and component management.
- It'll support a hierarchy of components (atomic and composite components).
- Connectors will be independent of a transport mechanism (SOA, IPC, etc.).
- The framework will be able to **control runtime reconfiguration** and **derive formal description** of architecture.

  - Basic Idea
- 3 The Framework
  - Vertical and Horizontal View
  - Behaviour
  - Dynamic Architecture

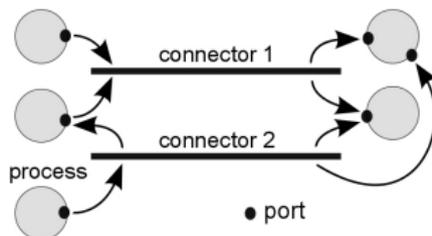

# Vertical View

## Modified Asynchronous Network Model (Modified ANM)

- Original ANM = directed graph of processes (nodes) communicating via channels (edges).
- Modified ANM = directed graph (compatible with the original ANM) where
  - nodes** are processes and connectors (processes, which only resend messages),
  - edges** are connections between processes and connectors and vice versa.

# Modified Asynchronous Network Model – 3 Layers (Vertical View)

**process layer** – atomic or composite components, responsible for an application logic,

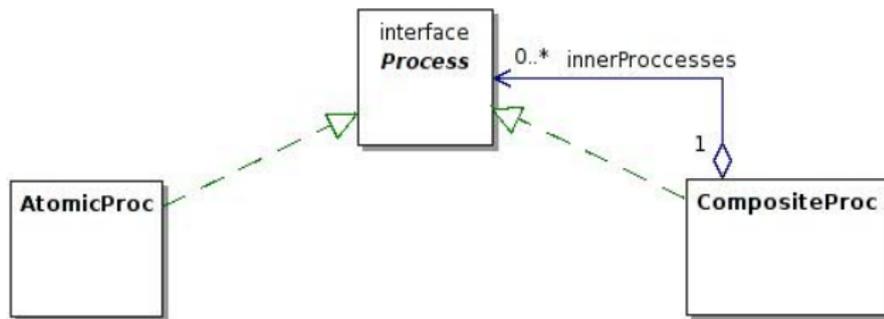

**connector layer** – connectors, a low-level communication support responsible for a reliable communication,

**port layer** – interfaces between the process and connector layer.

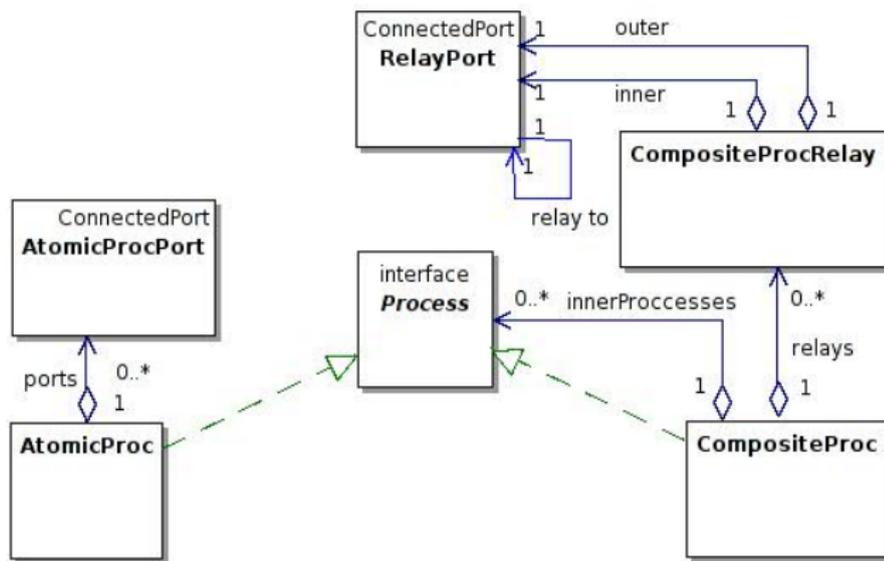

# Horizontal View

## Component-Based Architecture (Atomic and Composite Components)

## Component-Based Architecture (Atomic and Composite Components)

# A Calculus of Mobile Processes ( $\pi$ -Calculus)

## Introduction

- In 1992 by R. Milner, J. Parrow and D. Walker as modification of CCS.
- Algebraic approach to a system of concurrent and mobile processes.
- Only two concepts:
  - agents – communicating processes,
  - names – channels, data, (processes), etc.
- Key feature is **passing of names** – passing of parts of architecture.

# A Calculus of Mobile Processes ( $\pi$ -Calculus)

Behavioural Model of a System with Dynamic Architecture

**atomic components** –  $\pi$ -calculus processes defined at a design time, interfaces of components are channels from/to the processes.

**connectors** –  $\pi$ -calculus processes with channels for connected components defined as

$$\begin{aligned} \text{Connector}(p1_{in}, \dots, pn_{in}, q1_{out}, \dots, qn_{out}) = \\ \sum_{i=1}^n \sum_{j=1}^m qj_{out}(x) \cdot \overline{pi}_{in}(x) \cdot \\ \text{Connector}(p1_{in}, \dots, pn_{in}, q1_{out}, \dots, qn_{out}) \end{aligned}$$

**composite components** – parametric  $\pi$ -calculus process (parallel compositions of internal processes) with hidden internal channels and visible channels of interfaces of the composite components.

# Passing of Components and Connections

## In the $\pi$ -Calculus

- Dynamic architecture allows passing of components and connections (ports) as ordinary messages.
- In the  $\pi$ -calculus, it is trivial (see passing of port  $b$ , in the paper).
- In the framework, passing of connection to an interface of a component (a port)
  - = passing of reference to a connector, which is connected to the interface.
- After passing of a port, its environment has to be restored
  - = passed port is connected to the same connector as original port.

# Summary

- Distributed ISs create needs for component-based design with dynamic architecture.
- It is a problem to control runtime reconfiguration and reflect it at a design time.
- The presented framework provides runtime support for component-based systems with dynamic architecture.
- Outlook
  - Implementation of a prototype of the framework.
  - Case-study and its evaluation.
  - Final design and implementation.
